Layout with Flexbox

CSS display: flex property

The CSS display: flex property sets an HTML element as a block level flex container which takes the full width of its parent container. Any child elements that reside within the flex container are called flex items. Flex items change their size and location in response to the size and position of their parent container.

```
div {
   display: flex;
}
```

CSS display: inline-flex property

The CSS display: inline-

flex property sets an HTML element as an inline flex container which takes only the required space for the content. Any child elements that reside within the flex container are caleld flex items. Flex items change their size and location in response to the size and position of their parent container.

```
CSS flex-grow property
```

The CSS flex-grow property allows flex items to grow as the parent container increases in size horizontally. This property accepts numerical values and specifies how an element should grow relative to its sibling elements based on this value. The default value for this property is 0.

```
.container{
  display: inline-flex;
}
```

```
.panelA {
  width: 100px;
  flex-grow: 1;
}

/* This 'panelB' element
will stretch twice wider
than the 'panelA' element
*/
.panelB {
  width: 100px;
  flex-grow: 2;
}
```

CSS justify-content Property

The CSS **justify-content** flexbox property defines how the browser distributes space between and around content items along the main-axis of their container. This is when the content items do not use all available space on the major-axis (horizontally).

justify-content can have the values of flex-start, flex-end, center, space-between, and space-around.

Flexbox Properties align-items

When working with CSS flexbox alignitems is used to align flex items vertically within a parent container.

```
/* Items based at the
center of the parent
container: */
div {
    display: flex;
    justify-content: center;
}

/* Items based at the
upper-left side of the
parent container: */
div {
    display: flex;
    justify-content: flex-
start;
}
```

The CSS flex-shrink property

The CSS flex-shrink property determines how an element should shrink as the parent container decreases in size horizontally. This property accepts a numerical value which specifies the ratios for the shrinkage of a flex item compared to its other sibling elements within its parent container. The default value for this property is 1.

```
.container {
    display: flex;
}

.item-a {
    flex-shrink: 1;
    /*The value `1` indicates
that the item should
shrink.*/
}

.item-b {
    flex-shrink: 2;
    /*The value `2` indicates
that the item should shrink
twice than the element
`item-a`.*/
}
```

Css flex-basis property

The flex-basis CSS property sets the initial base size for a flex item before any other space is distributed according to other flex properties.

```
// Default Syntax
flex-basis: auto;
```

Css flex property

order on a single line.

The flex CSS property specifies how a flex item will grow or shrink so as to fit within the space available in its flex container. This is a shorthand property that declares the flex-grow, flex-shrink, and flex-basis properties in that

```
// Three properties
declared on three lines:
.first-flex-item {
   flex-grow: 2;
   flex-shrink: 1;
   flex-basis: 150 px;
}

// Same three properties
declared on one line:
.first-flex-item {
   flex: 2 1 150px;
}
```

Css flex-wrap property

The flex-wrap property specifies whether flex items should wrap or not. This applies to flex items only. Once you tell your container to flex-wrap, wrapping become a priority over shrinking. Flex items will only begin to wrap if their combined flex-basis value is greater than the current size of their flex container.

Css align-content property

The align-content property modifies the behavior of the flex-wrap property. It determines how to space rows from top to bottom (ie. along the cross axis). Multiple rows of items are needed for this property to take effect.

```
.container {
  display: flex;
  flex-wrap: wrap;
  width: 200px;
}
```

Css flex-direction property

The **flex-direction** CSS property specifies how flex items are placed in the flex container - either vertically or horizontally. This property also determines whether those flex items appear in order or in reverse order.

div { display: flex; flex-direction: rowreverse; }

The CSS flex-flow property

The CSS property flex-flow provides a shorthand for the properties flex-direction and flex-wrap. The value of the flex-direction property specifies the direction of the flex items and the value of the flex-wrap property allows flex items to move to the next line instead of shrinking to fit inside the flex container. The flex-flow property should be declared on the flex container.

```
// In this example code
block, "column" is the
value of the property
"flex-direction" and "wrap"
is the value of the
property "flex-wrap".

.container {
   display: flex;
   flex-flow: column wrap;
}
```
